ABSTRACT

Introduction Diet and nutrition are leading causes of global morbidity and mortality. Our study aimed to identify and synthesise evidence on the association between food environment characteristics and diet, nutrition and health outcomes in low-income and middle-income countries (LMICs), relevant to urban settings, to support development and implementation of appropriate interventions.

Methods We conducted a comprehensive search of 9 databases from 1 January 2000 to 16 September 2020 with no language restrictions. We included original peer-reviewed observational studies, intervention studies or natural experiments conducted in at least one urban LMIC setting and reporting a quantitative association between a characteristic of the food environment and a diet, nutrition or health outcome. Study selection was done independently in duplicate. Data extraction and quality appraisal using the National Heart Lung and Blood Institute checklists were completed based on published reports using a prepiloted form on Covidence. Data were synthesised narratively.

Results 74 studies met eligibility criteria. Consistent evidence reported an association between availability characteristics in the neighbourhood food environment and dietary behaviour (14 studies, 10 rated as good quality), while the balance of evidence suggested an association with health or nutrition outcomes (17 of 24 relevant studies). We also found a balance of evidence that accessibility to food in the neighbourhood environment was associated with diet (10 of 11 studies) although evidence of an association with health outcomes was contradictory. Evidence on other neighbourhood food environment characteristics was sparse and mixed. Availability in the school food environment was also found to be associated with relevant outcomes. Studies investigating our other primary outcomes in observational studies of the school food environment were sparse, but most interventional studies were situated in schools. We found very little evidence on how workplace and home food environments are associated with relevant outcomes. This is a substantial evidence gap.

Key questions

What is already known?

- There is growing evidence from high-income settings that food environments drive behaviour, nutrition and health outcomes.
- We don't know how, or which aspects of, food environments may be impacting populations in low-income and middle-income countries.

What are the new findings?

- This systematic review is the largest known compilation of evidence on the impact of the food environment on health in low-income and middle-income countries, compiling experimental and observational studies to illuminate areas where the evidence is consistent, where it is contradictory, and where it is lacking.
- The balance of evidence suggests that availability and accessibility domains of the food environment are associated with diet, nutrition and/or health outcomes, while evidence on the impact of prices, vendor and product properties, marketing and regulation is sparse and mixed.

What do the new findings imply?

- Our synthesis can be used to support policy and practice activities to change the availability of healthy and unhealthy food in the neighbourhood environment, particularly in middle-income countries; examples would be zoning laws or healthy food carts.
- Affordability and social environment ('desirability') interventions appear to be potentially interesting and worthwhile avenues to pursue (little but consistent evidence).
- More research is required to understand the impact of workplace and home food environments, vendor and product properties in neighbourhoods and schools, and intervention studies in lower middle-income and low-income countries.

Conclusion 'Zoning' or 'healthy food cart' interventions to alter food availability may be appropriate in urban LMIC.

PROSPERO registration number CRD42020207475.

INTRODUCTION

Diet and nutrition are among the leading causes of global illness, disability and death; in 2017, 1 in 5 deaths and 255 million disability-adjusted life-years were attributed to dietary risk factors.¹ This is largely due to the contribution of dietary risk factors to development of non-communicable diseases (NCDs). The health and economic impacts of NCDs in low-resource settings are disproportionately high²⁻⁴; around 80% of NCD deaths occur in low-income and middle-income countries (LMICs).⁵ Diet also plays a role in wider morbidity and mortality, including from infectious diseases.^{6,7}

The food environment includes 'physical, economic, policy and sociocultural surroundings, opportunities and conditions' that are likely to drive dietary behaviour, nutrition and health.⁸ Systematic reviews of evidence from high-income countries (HICs) have found evidence of associations between availability of specific categories of food outlets and dietary and health outcomes,⁹⁻¹² as well as evidence suggesting associations between other characteristics of the food environment (eg, affordability, marketing and regulation) and dietary and health outcomes.^{12,13} These have driven policy-makers to intervene and attempt to regulate the food environment to improve health outcomes.^{14,15}

Globalisation and international trade are homogenising environments and infrastructure worldwide, however, there are still important differences in the food environments, and the way that populations interact with these, between HICs and LMICs.¹⁶ For this reason, despite an existing evidence base on the association between the food environment in HICs and diet, nutrition and health outcomes, it is important to also investigate and synthesise evidence from LMICs.

Fifty-five per cent of the world population lives in urban settings, and this figure is projected to rise to 70% by 2050.¹⁷ There are differences between urban and rural LMIC settings relating to the food environment, dietary behaviour and health. In urban LMIC, individuals are more likely to buy than grow food for their own consumption and a number of distinct barriers exist which may reduce access to healthy food, such as more expensive fresh food.¹⁸ There is evidence that diets, dietary behaviour and related health outcomes may be poorer in urban LMIC settings than in rural LMIC settings. The global burden of disease study noted a marked difference between obesity prevalence in rural and urban populations¹⁹ and a more recent review highlights higher prevalence of central obesity in urban residents.²⁰ A systematic review and meta-regression found an association between urbanicity and obesity prevalence in Southeast Asia.²¹ Further systematic reviews and meta-regression

analyses have found that in sub-Saharan Africa, urban residents are more likely to consume salt and less likely to consume vegetables than rural residents.^{22,23} A 2015 study of 74 Latin American countries found that sales of ultraprocessed products were larger in more urbanised countries.²⁴

Context-specific research is required to understand how the food environment in urban LMIC can support or hinder the diet and health of LMIC populations, to support development of appropriate interventions. LMIC policy-makers need to see evidence that resonates with them to justify taking steps to intervene in the food environment.

Aim

The aim of our study is to identify and synthesise evidence that reports associations between the characteristics of the food environment and diet, health and nutrition outcomes or effects of food environment interventions on these outcomes, in LMICs that are relevant to urban settings.

METHODS

A theoretical framework for conceptualising the LMIC food environment

We have adopted Turner *et al*'s¹⁶ conceptual model of the food environment, developed through a series of iterative, international congregations with experts in nutrition and public health. In this conceptual model, the food environment is situated within the broader food system. The model relates four external domains (food availability, prices, vendor and product properties, marketing and regulation) to four personal domains (food accessibility, affordability, convenience and desirability).¹⁶ For this review, we are most interested in the external domains of the food environment. However, we also conceive of accessibility (which in Turner's model includes physical distance to food vendors and individual activity spaces) and affordability (purchasing power) as concepts of interest. This is reflected in our study eligibility criteria and further details are in tables 1 and 2.

Search strategy and selection criteria

For this systematic review, we conducted a comprehensive search of nine databases: MEDLINE, EMBASE, Global Health, Econlit, Web of Science, Scopus, CINAHL, PsycINFO and Applied Social Sciences Index and Abstracts on 16 September 2020 to identify relevant studies. We did not apply any language restrictions, but restricted the search to studies published since the year 2000. The search strategy was based on those published in Turner *et al*,²⁵ adapted by two researchers (OO and SW) and an academic librarian. The search terms used in MEDLINE are presented in online supplemental table 1).

After completion of searches, retrieved records were exported to an EndNote library, duplicates were removed and records were then imported and managed using the

Table 1 Eligibility criteria

Domain	Inclusion criteria	Exclusion criteria
Population/setting	Must feature one or more urban LMIC setting according to the World Bank Data (2020) classification of countries. ¹⁰⁶	High-income country settings or high-income country and LMIC settings in which it is impossible to disaggregate the LMIC findings. Exclusively rural settings.
Exposure/intervention	One or more of six food environment characteristics defined in table 2 (Availability, Price, Vendor and Product Properties, Marketing and Regulation, Accessibility and/or Affordability). We also collected data on quantitative associations between two further food environment characteristics (Convenience or Desirability) and our outcomes of interest. However, if papers reported associations between these food environment characteristics and our outcomes of interest only, they were excluded.	Do not include relevant exposures.
Outcomes	Must report a quantitative association between a food environment characteristic (as described in exposure/intervention) and: Any health outcome (eg, prevalence of obesity, hypertension, diabetes or any other health outcome) or Diet/ dietary behaviour outcome (eg, foods bought or consumed) or Nutrition outcome (energy intake, macronutrients or micronutrients consumed)	Do not include relevant outcomes or do not include associations between the exposure/intervention of interest and relevant outcomes.
Study design	Quantitative or mixed-methods observational studies (cross-sectional, case-control, longitudinal cohort and mixed-methods studies) or intervention studies (including trials, interrupted time series or other intervention study designs) and natural experiments will be included.	Reviews including systematic reviews Qualitative studies
Publication type	Original peer-reviewed published articles	Protocols, full theses, case series and case reports. Conference abstracts.

LMIC, low-income and middle-income country.

online platform Covidence. A predefined list of inclusion and exclusion criteria ([table 1](#)) was used to sift titles and abstracts in duplicate (SW, IG, HMJ, DM, NA, LA-K and OO), with any study assessed as potentially relevant by either reviewer (or both) retrieved in full for text assessment. Formal eligibility assessment was done in duplicate (SW, IG, AI, HMJ, DM, NA, RI and OO) with disagreements resolved by a third reviewer (OO or SW). Further screening of the reference lists of included studies was also completed by one reviewer (SW).

The protocol for this study was registered online with the PROSPERO database: (CRD42020207475).²⁶

Data analysis

We extracted data into a predetermined and piloted data extraction form on Covidence. We extracted data on study characteristics (citation; study design, duration and timing; setting), participant characteristics, details of the food environment characteristics examined including how these were assessed, details of the health, details of the diet or nutrition outcomes including definition and assessment method and key findings including statistics such as effect sizes as reported.

We conducted quality appraisal using the National Heart Lung and Blood Institute checklists relevant to the study design pertaining to the outcomes of interest (eg, for a mixed-methods study which reported a cross

sectional association between a food environment characteristic and a health, diet or nutrition outcome, we would use the checklist for cross sectional studies). Quality was rated good, fair or poor.

Seven studies were abstracted and quality appraised in duplicate, with any variation between extractions resolved by one reviewer (OO). There were no inconsistencies between extractions and so the majority of data extraction and quality appraisal were completed by one reviewer (SW, IG, HMJ, FS, AI or OO) and checked by a second reviewer (SW or OO).

We synthesised identified literature by subdividing the studies into groups first into observational studies and interventional studies. For the synthesis of observational studies, we grouped them based on the food environment characteristics examined, and within these groups, we further subdivided studies into those reporting health, nutrition or diet outcomes respectively. We did not try to standardise the exposures or outcomes of the observational studies. Instead we were most interested in whether an association was reported between the characteristic and an outcome. For the interventional studies we synthesised the findings by comparing the outcomes from studies with elements targeting similar food environment characteristics. We did not apply Grades of Recommendations, Assessment, Development and

Table 2 Characterisation of the food environment, adopted from Turner *et al*¹⁶

Turner concept	External					Internal			
	Availability	Prices	Vendor and product properties	Marketing and regulation		Accessibility	Affordability	Convenience	Desirability
Turner definition	Presence of food sources or products	Monetary value of food products	Vendor properties (typology, opening hours, services) and product properties (food quality, composition, safety, level of processing, shelf-life, packaging)	Promotional, information, branding advertising, sponsorship, labelling, policies		Physical distance, time, space and place, individual activity spaces, daily mobility, mode or transport	Purchasing power	Relative time and effort of preparing, cooking and consuming food product, time allocation	Preferences, acceptability, tastes, desires, attitudes, culture, knowledge and skills
Primary outcomes									
Examples from the identified literature	Density of food retail outlets of various types. Counts of food retail outlets. Presence of food retail outlets of various types. Availability of specific food items at school or home.	Monetary value of fruit, vegetables, sugar-sweetened beverages, ultraprocessed food, apples.	Quality of fruit and/or vegetables. Commercial vendor within a school or non-commercialised food environment.	Billboard advertising of various types. Advertising within food retail locations. Provincial school policies. Individual school policies. School status as a health promoting school. Workplace policy		Living near a fast-food outlet. Perceived local food availability of various types. Perceptions of ease of access to retail outlets of various types.	'I can buy fruit and veg even when they are expensive'. The cost of two servings of fruit and three of vegetables per day relative to household income.	'I have time to prepare and eat Fruit and veg' 'Fruit and veg are easy to prepare for me'	Preferences measured using Likert scales 'I like it very much' to 'I have not tried it' Culture ▲ Survey questions such as: 'Parents remind me to eat' 'Parents pressure me to eat', everyday we eat on time' 'We watch TV during a meal' ▲ Family support ▲ Attitude of manager

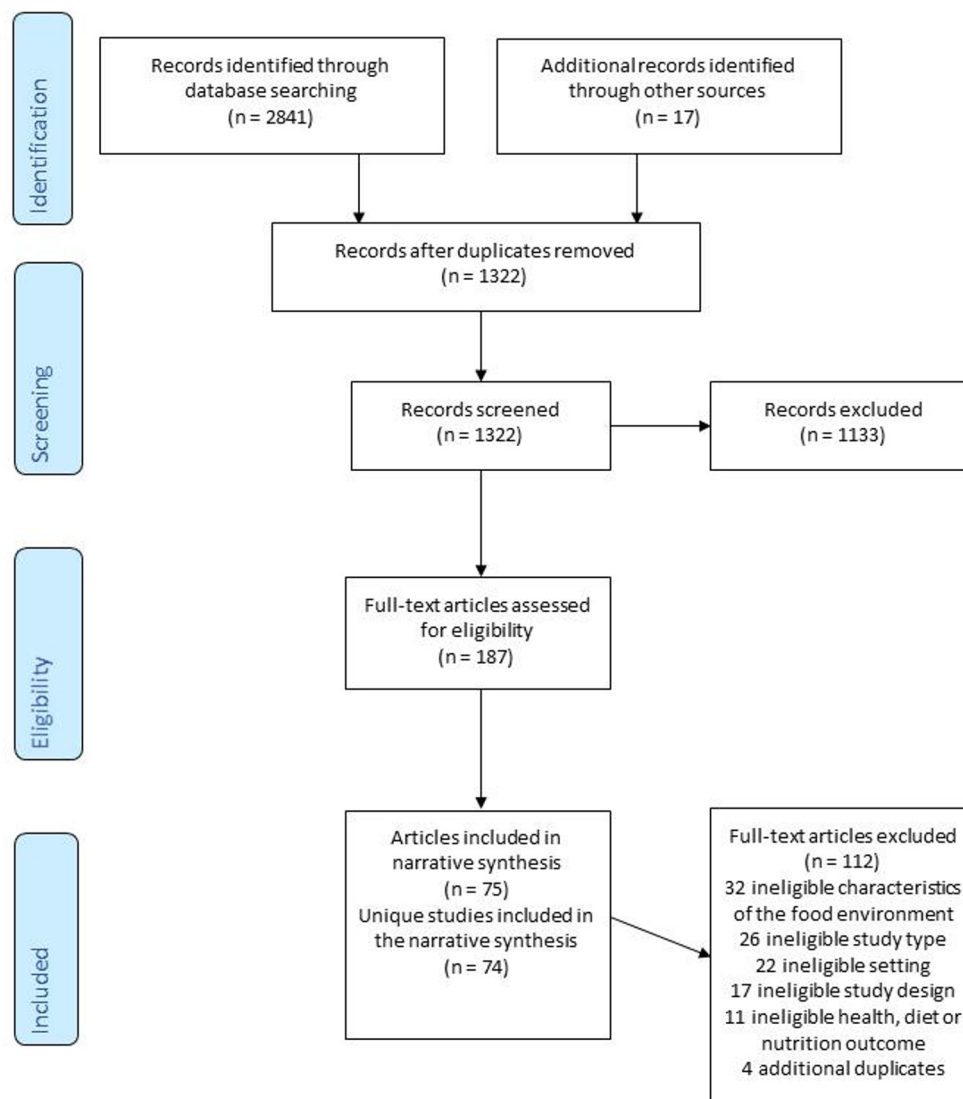

Figure 1 PRISMA flow diagram. PRISMA, Preferred Reporting Items for Systematic Reviews and Meta-Analyses.

Evaluation to assess the certainty of the evidence from the identified trials, because of the heterogeneous nature of the complex interventions in these, and the type of recommendations we were seeking to make.

We reported the study according to Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines.²⁷

Role of the funding source

The funders of the study had no role in study design, data collection, data analysis, data interpretation or writing of the report. The corresponding author had full access to all the data in the review and had final responsibility for the decision to submit for publication.

RESULTS

Search results

Figure 1 provides the PRISMA diagram and reasons for exclusion. Searches identified 2858 records. Titles and abstracts of 1322 were screened, including 1305 deduplicated records identified through database searching

and 17 records identified through reference screening of included studies. We identified 187 articles for full-text review of which 75 articles met eligibility criteria and were included in this systematic review. For a full list of excluded studies, please see online supplemental table 3).

Description of included studies

Tables 2 and 3 describe the characteristics of the observational and interventional articles included, respectively. Identified studies were published between 2010 and 2020 and included data collected from the year 2000 onwards (although a few studies did not report when data collection occurred). In total 29 countries were represented in the data included in this systematic review, including both higher and lower middle income countries (26 and 20 represented, respectively), as well as low-income countries (three represented: Malawi, Sudan and Syria, all included within multicountry studies).

Sixty-seven included articles reported 67 unique observational studies, comprised of 6 multicountry studies and

61 focused on one country (table 3). Of those focusing on one country, 28 were based on data from Brazil, 16 from China, two from each of Vietnam, Ghana, Mexico and India. The multi-country studies included two focused on nine countries of the former Union of Soviet Socialist Republics, one examining data from South Africa and Ghana, one study of multiple European countries, from which we extracted data from Bulgaria (the only LMIC included), and two studies of multiple LMICs (one of which also included HICs). Figure 2 shows the countries covered by observational studies included in our review.

The observational studies covered the food environment in the home (n=2), school (n=13) and neighbourhood (n=50) setting. With one additional study examining both the home and school environment²⁸ and one further study investigating the food environment in the workplace setting.²⁹ Most used a cross sectional design for investigating the association between the food environment and health, diet or nutrition outcomes (n=63) although these were sometimes nested in a cohort study, or one part of a mixed-methods study.^{30–32} Three studies used cohort study designs, all from Chinese settings.^{33–35} One study used a case–control design.³⁶

Study populations included adults and children. Associations were presented between food environment characteristics and diet (n=35), health (n=36) and nutrition (n=3) outcomes, in which three studies examined both

diet and health outcomes, one study examined diet and nutrition outcomes and one study examined all three.

The eight interventional articles reported seven unique studies. These include two studies from Iran (one cross-sectional study and one cluster randomised controlled trial (RCT)), one cluster RCT from Brazil, one controlled study from South Africa and one cluster RCT from Thailand (table 4). Additionally, there were two reports of the same cluster RCT carried out in Mexico and a further Mexican cluster RCT. All of these studies are from upper-middle-income countries. All of the included articles report interventions based in schools, except the study in Brazil which evaluates a workplace intervention. Interventions ranged in duration from 4 weeks to ~4 years (in the Iranian cross-sectional study which examined the Iranian Health Promoting Schools programme which was set up in 2011 and the evaluation data collected in 2015). All studies reported the effect of the intervention on dietary outcomes except for one Mexican study which reported health outcomes only.³³ The second Mexican study and the Thai study additionally reported health outcomes, and the Iranian cluster RCT and South African study additionally reported nutrition outcomes.

Of the included observational studies 42 were rated good, 17 were rated fair and 8 were rated poor (table 5). Further details of our quality appraisal are included in online supplemental table 2. The intervention studies were rated poor (n=3) and fair (n=4) (table 6). Further details on the quality appraisal are presented in online supplemental table 2.

Associations reported in the literature

Fifty observational studies reported associations between neighbourhood food environment characteristics and diet, nutrition or health outcomes. Forty-seven of these were cross-sectional and three were cohort studies.

Neighbourhood availability

Thirty-six of the observational studies (2 cohort studies and 34 cross-sectional studies) examined the association between an availability variable and outcome of interest, of which 26 examined availability alone. The majority of these were investigating the presence, density or number

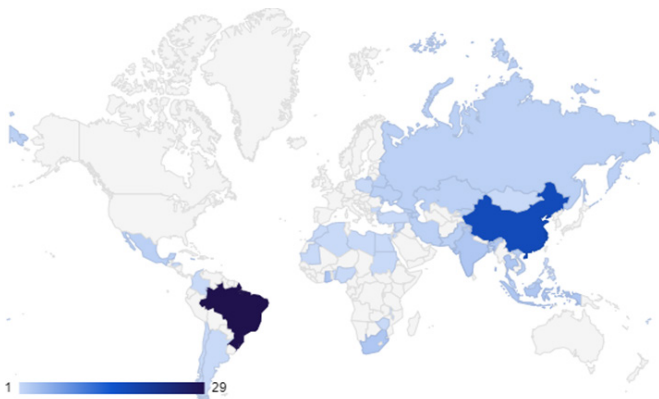

Figure 2 Map to show countries covered by observational studies included in our review.

Study design cRCT: food environment characteristics.

Given the heterogeneity in study design, methodology, exposure and outcomes, we have performed a narrative synthesis.

The characteristics of the food environment investigated in the included studies are further described in table 2.

Av, availability; BMI, body mass index; cRCT, cluster randomised controlled trial; D, desirability; M&R, marketing and regulation; N, nutrition; outcome H, health; V/P, vendor or product properties.

of food retail outlets of various types with their outcomes of interest.

Two cohort studies, both fair-quality, found significant associations between an availability variable and relevant outcome, one with a nutrition outcome,³⁴ and one with a health outcome.³⁵ Of those cross-sectional studies investigating an availability variable, 10 good studies found significant associations between availability and dietary outcomes^{37–46} as did one poor study.⁴⁷ Two further fair quality studies reported associations between availability and dietary outcomes although without presenting whether this was statistically significant.^{48 49}

Further, 10 good studies found a significant association between an availability characteristic and a health outcome^{50–59} as did 2 fair studies^{60 61} and 1 further poor study.⁶² Additionally, one poor study reported that prevalence of overweight and mean body mass index (BMI)

trended in the same direction as the number of ‘western-style’ restaurants and convenience stores, however, no statistics were presented.⁶³ Two further good studies suggested that availability characteristics were important for childhood obesity prevalence.^{64 65} In contrast, five good studies did not find an association between availability and health outcomes^{40 45 66–68} and one additional fair study did not find an association between availability and health outcomes.⁶⁹ Further, one poor study did not identify an association between availability and health (hypertension or diabetes).⁷⁰

In summary, identified studies provide good evidence that the food available in the neighbourhood is associated with diet, and the preponderance of evidence suggests that the food available in the neighbourhood is also associated with nutrition and health outcomes.

*Outcome Y: yes, at least one significant outcome was reported; N: no a significant outcome was not reported; O: other.

†Quality: G: good, F: fair, P: poor.

Neighbourhood accessibility

The next most investigated aspect of the neighbourhood food environment was accessibility included in 18 studies, 1 cohort and 17 cross-sectional. Identified studies provide good evidence that food accessibility is associated with diet, but conflicting evidence of the association between accessibility and health, with no evidence of the association between accessibility and nutrition.

One cohort study of fair quality found an association between accessibility and dietary outcomes.⁷¹

Six good cross-sectional studies found accessibility was associated with diet^{38 39 72–75} as did a further three fair studies^{76–78} and one poor study.⁴⁷ However, one further good cross-sectional study found no association between dietary quality and geographical proximity to different formal retail outlets.³²

Just two good studies, both cross-sectional, found accessibility was associated with health. A 10 km increase in the distance from a supermarket was associated with a 1.7 kg/m² higher means BMI (p=0.02) in the middle class in

Quality: G: good, F: fair, P: poor.

*Outcome Y: yes, a significant outcome was reported; N: no a significant outcome was not reported; O: other.

Acc, accessibility; Aff, affordability; Av, availability; Conv, convenience; D, desirability; M&R, marketing and regulation; V/P, vendor or product properties.

Jamaica⁵³ and participants who did not report commercial places such as shops, stores and markets to be within walking distance of their homes were 49% more likely to be overweight than those who reported proximal facilities in Maiduguri, Nigeria.⁷⁹ However, one additional poor study found an association between accessibility and health.⁸⁰ In contrast one good study,⁷⁴ two fair studies^{69 81} and one poor study⁷⁰ found no association between accessibility variables and health outcomes.

Neighbourhood price

Price was examined in four studies all of which were cross-sectional. One good study did not find that price was associated with fruit and vegetable consumption or sugar-sweetened beverage consumption.³⁸ Two further fair studies did not find an association between price and health outcomes. One of these found that fruit and vegetable price or ultraprocessed food price was not associated with overweight⁶⁰ and the other that the price of apples was not associated with obesity.⁶⁹ In contrast, one good study found that a 1% increase in the price of ultraprocessed foods acquired at supermarkets would lead to a 0.59% decrease in purchases and this price-elasticity was significant.⁸²

Neighbourhood marketing and regulation

Marketing and regulation characteristics were examined at the neighbourhood level in five cross-sectional studies. One good study found billboard advertising of snacks was negatively related to daily fruit or vegetable consumption for men and women, although the same study found that women's daily fruit and vegetable consumption was higher in areas with more billboards advertising soft drinks.³⁹ However, two fair studies did not find this translated to an association with health outcomes.^{60 69} One did not find an association between fruit and vegetable advertising or ultraprocessed food advertising within

food retail locations situated in each neighbourhood and overweight.⁶⁰ The other did not find an association between unhealthy food advertising and obesity. Two good studies found that provincial school policies were important factors for modelling prevalence of childhood obesity.^{64 65}

Neighbourhood vendor and product properties

Two cross-sectional studies examined vendor and product properties at the neighbourhood level. One good study found that the quality of vegetables in commercial establishments was associated with higher consumption of fruit and vegetables,⁴² while one fair study found that the quality of fruit and vegetables on offer in local food retail outlets was not associated with overweight.⁶⁰

Neighbourhood affordability

Affordability was examined at the neighbourhood level in two studies both of which found an association with dietary outcomes. One good study found that combined fruit and vegetable intake decreased as the relative cost of two servings of fruits and three servings of vegetables per day increased in communities across 15 LMIC.⁸³ One fair study found that participants perception of affordability (the answer to 'I can buy FV even when they are expensive') was associated with fruit and vegetable intake.⁷⁷

Neighbourhood convenience

Three cross-sectional studies examined convenience characteristics all of which found an association between convenience and dietary outcomes. In one good study, a convenience variable examined the number of food items purchased at supermarkets and found that an increase was associated with an increase in calorie acquisition from ultraprocessed foods and beverages. Responses to 'I have time to prepare and eat' and 'Fruit and vegetables are easy to prepare for me' were associated with higher

fruit and veg consumption in one fair study.⁷⁷ One poor study found refrigerator ownership is positively correlated with dietary variety.⁴⁷

Neighbourhood desirability

Two cross-sectional studies examined desirability at the neighbourhood level, one good and one fair, both of which found an association with diet.^{73 78}

School availability

Fourteen observational studies examined an association between a school food environment characteristics and diet, nutrition or health outcome, 1 case-control study and 13 cross-sectional studies.

One poor case-control study³⁶ found that availability was associated with health outcomes. Ten cross-sectional studies examined the association between availability and an outcome of interest. Three good cross-sectional studies^{84–86} and two fair cross-sectional studies^{87 88} found an association between an availability characteristic and a health outcome.

One good study found an association between availability and dietary outcomes⁸⁹ with two additional fair studies that found an association with a dietary outcome.^{30 31} However, one good study did not find an association between availability (presence of a school canteen) and dietary behaviour (unhealthy snacking).⁹⁰

School marketing and regulation

The second most common aspect of the school environment studied was marketing and regulation, investigated by three good studies. One found an association between presence of a school fruit and vegetable policy and fruit and vegetable consumption across schools from 24 countries,⁹¹ however, another found no association between the schools status as part of the Iranian Health Promoting Schools programme and unhealthy snacking behaviour.⁹⁰ The third study found no association between school food policy and BMI.⁸⁵

School vendor and product properties

One fair study examining vendor and product properties was looking specifically at vendor properties, finding that students of schools that offered meals prepared on the premises had lower prevalence of obesity than those who studied where meals were not offered (summarised under availability above). However, where the food was commercialised, obesity prevalence was significantly higher than where there was no commercialisation of foods with a similar association with prevalence of hypertension.⁸⁷

School accessibility

Two good cross-sectional studies examined accessibility. One found an association with a dietary outcome⁹⁰ while the other found no association.²⁸

School desirability

Three studies investigated desirability. Two examined associations with diet: One good study found the social norms pressure was associated with unhealthy snacking⁹⁰ and one good study found an association between 'preferences' and vegetable intake. One poor study found peer influence was associated with a health outcome: overweight.⁸⁸

Other school environment

Finally, there was one poor study of the school food environment in which we were unable to categorise the characteristics investigated as the methodology simply stated that the researchers used 10 questions to collect data on school environment without giving details of the questions.⁹² This study reported no association between the 'school environment' and BMI.

Workplace environment

A single cross-sectional study examined the workplace food environment and dietary outcomes.²⁹ The study found no association between workplace policy ('Marketing and Regulation') or the attitude of management (considered part of workplace 'culture' and therefore classified as 'Desirability') and eating practices across 26 factories. However, they did find an association between workplace nutrition environment ('Availability' and 'Marketing and Regulation') and individual worker attitude and dietary behaviour suggesting that the more supportive workplace nutrition environment alongside a positive individual attitude to health, the less frequently unhealthy food is consumed.

Home environment

Finally, three cross-sectional studies examined the home food environment. Two good studies found that accessibility and desirability elements were associated with dietary behaviour in adolescents.^{28 93} One of these additionally found that convenience was associated with dietary behaviour.²⁸ Desirability was also associated with obesity in adolescents in one poor study, as was availability.⁹⁴

Effects reported in the literature

All of the interventional studies identified were complex interventions with more than one element, sometimes multiple elements altering more than one characteristic of the food environment, and sometimes additional elements which did not target the food environment (eg, educational components). One fair⁹⁵ and one poor quality study⁹⁶ evaluating school interventions with elements of availability, marketing and regulation, and desirability found that these improved diet, nutrition and/or health.

Four studies examined school interventions with elements of availability and/or marketing and regulation without desirability elements. One fair⁹⁷ and one poor-quality study⁹⁸ found no effect on diet and/or nutrition of these interventions, while similar interventions were

found to have an effect on health in one fair quality study,³³ and on health but not diet in an additional fair quality study (table 6).⁹⁹

A study of an intervention which included a marketing and regulation approach, among other elements, in a workplace found that this had a beneficial effect on health (table 6).¹⁰⁰

DISCUSSION

This review identified 74 studies including data from 29 countries, investigating the association between food environment characteristics and diet, nutrition and health outcomes in LMICs. All the intervention studies identified were carried out in upper-middle-income countries, observational studies also covered lower-middle and low-income countries (three countries included within multi-country studies). With the great majority of evidence coming from middle-income countries, it is worth considering the extent to which the findings can be generalised to low-income countries. The strongest recommendations from this review arise from the consistent evidence identified (14 studies, 10 of which were rated as good quality) of an association between availability characteristics in the neighbourhood food environment and dietary behaviour, as well as a balance of evidence suggesting an association with health or nutrition outcomes (17 out of 24 relevant studies). This suggests that interventions to increase the availability of healthy food options at the neighbourhood level, or to decrease the availability of unhealthy food are promising and worth investigating. It might be that availability of healthy and unhealthy food options in the neighbourhood is more important in LMIC than in some HIC, as a recent review on this topic focused on the USA and Canada only, included 71 studies and found that associations between food outlet availability and obesity were predominantly null.¹¹ However, they did also find some patterns in the non-null studies suggesting an association between certain food outlets and adult obesity, and more recent studies (including longitudinal studies) support an association between availability and relevant outcomes.^{101 102} If there is a difference between HIC and LMIC settings, it may be due to differences in socioeconomics factors as well as mobility (due to ownership of motorised vehicles or efficient public transport) which makes it easier to access food outside the neighbourhood local to an individual's residence in HIC than LMIC. No interventional study examining this element of the neighbourhood food environment relevant to urban LMIC settings was identified by our search. Interventions that have been implemented in HIC include 'zoning powers' given to local authorities to enable them to control the food environment through regulating land use—for example, limiting certain food outlets from trading in specific areas. In addition, 'healthy food carts' have been used to increase availability to healthy food in deprived urban neighbourhoods with some success.¹⁰³ Therefore, a key implication for

research and policy would be to begin to implement and evaluate similar interventions in LMIC.

We also found a balance of evidence that accessibility to food in the neighbourhood environment was associated with diet (10 out of 11 studies) although there was no evidence of an association with nutrition outcomes and the evidence of an association with health outcomes was contradictory. Again, we did not identify any interventional studies focused on this element of the neighbourhood food environment and would suggest that there is enough evidence that this may be promising and worth further investigation. Interventions are likely to be similar to those addressing availability (eg, 'zoning' and 'healthy food carts') but could also include increasing accessibility to healthy food outlets, for example, by rerouting public transport links.

Evidence on vendor and product properties, price, and marketing and regulation at the neighbourhood level was sparse and mixed; while evidence on affordability examined at the neighbourhood level was sparse but consistent, two studies both found an association with dietary outcomes. Literature from HIC does support affordability as important for driving dietary and health outcomes, for example, in quantitative studies¹⁰⁴ and reported by participants in the qualitative literature.¹³ Further research is recommended to expand the evidence base on the association between these aspects of the neighbourhood food environment and diet, nutrition and health outcomes.

In keeping with the neighbourhood-level results, 12 observational studies examining availability elements in the school food environment and relevant outcomes found a balance of evidence in favour of an association. Twelve studies consistently identified an association between availability and a health outcome, three out of four studies reported an association between availability and a dietary outcome. The second most common aspect of the school food environment studied was marketing and regulation, investigated by three good studies, but with conflicting findings. Studies investigating our other primary outcomes in observational studies of the school food environment were sparse. We also identified six studies evaluating interventions in the school food environment. All the interventions studied were complex consisting of multiple elements. Two studies that evaluated interventions with elements of availability, marketing and regulation, and desirability found that these improved relevant outcomes whereas four studies investigating similar interventions without desirability elements had mixed results. A systematic review and meta-analysis of school food environment policies identified 91 interventions from the USA, Canada, Europe and New Zealand. This study reported that direct provision of healthy food and drinks (ie, availability interventions) were able to improve some dietary behaviours as were implementation of food, beverage or meal standards (ie, marketing and regulation intervention) although there were mixed findings on health and nutrition outcomes.¹⁴ A meta-analysis of six studies

investigating multicomponent behavioural and environmental interventions in schools in LMIC suggested an overall effect on change in BMI, whereas meta-analysis of five studies which examined BMI found no observed effect.¹⁰⁵ Certainly our findings suggest that further research is needed, but it is also likely that interventions to increase availability of healthy food or to reduce availability of unhealthy food in schools would have a beneficial effect on diets, with the effect on health requiring further investigation.

We found very little evidence from either observational or intervention studies on how workplace food environments and the home food environments are associated with health, diet or nutrition outcomes. This is a substantial evidence gap.

Although we rated many identified studies as 'good', the majority of observational studies did take a cross-sectional approach, so due to study design there are inherent weaknesses, even if they were well conducted. Future studies with longitudinal designs, and more controlled intervention studies (including cluster randomised designs) would provide stronger evidence to support future policy decisions.

We used a framework developed through a series of iterative, international congregations with experts in nutrition and public health.¹⁶ However, our own research team did not feel that the 'convenience' and 'desirability' concepts mapped well to our own concept of the food environment. Although we have synthesised evidence on convenience and desirability elements in the papers identified, we did not prioritise papers focused on these elements for inclusion so cannot draw strong conclusions. However, at the neighbourhood level both convenience and desirability characteristics were consistently associated with relevant outcomes in six included observational studies, and in school and home food environments a consistent association was seen between desirability and relevant outcomes. Further, two school food environment interventions with elements of desirability have a beneficial effect on outcomes. This does suggest that it might be worth considering desirability as a future target for intervention, suggesting an important role of the social environment on diet, nutrition and health outcomes in LMIC populations.

The major strength of this study is the rigorous systematic approach to identifying literature, including a search strategy developed with an academic librarian and careful reference screening of all included studies. The chances of reviewing bias are low because we did not limit by language and although we limited by year (to studies published from the year 2000 onwards) the earliest published study we found was published in 2010 so we are unlikely to have missed many earlier studies. The sensitivity of our approach is clear as we have identified more than thrice the number of articles of a recent scoping review on this topic.²⁵ We conducted selection of studies in duplicate by two independent reviewers, with data extraction and quality appraisal conducted by

one reviewer and checked by a second, which will have improved the reliability of the data synthesised.

In conclusion, interventions that increase the availability of healthy food and/or decrease the availability of unhealthy food are promising and are likely to have beneficial effects on dietary behaviour and healthy of LMIC populations and there is enough evidence to justify policy and practice implementation on this theme, with evaluation of the outcomes alongside these if possible. More longitudinal and interventional studies are required to inform further recommendations, with affordability and the social environment potentially interesting and worthwhile avenues to pursue.
